IMPROVEMENTS IN AND RELATING TO ACCESS CONTROLField of the Invention

5 The present invention relates to access control devices and methods.

Background to the Invention

10 Password protection is often used to control access to data or software as a result of which considerable attention has been paid to the breaking of password protection.

15 Referring to Figure 1 of the drawings that follow, there is shown a representative flow diagram of a prior art password protection method, according to which a corresponding device operates. In the Figures the abbreviation "PW" is used for "password".

20 At 100 a selected password is entered. The password may be user-selected or allocated in some other way.

25 The selected password is stored (102) at a memory location within the device. The device then enters its normal operation (104) as part of which it determines as each access request is submitted whether this is a password protected access (106). If it is not a password protected access, the "NO" branch is followed and normal operation resumes. If it is a password protected access, the "YES" branch is followed and a password is requested (108). Upon input of a password, the input password is compared (110) with the password stored at a memory location. If the

30

input password is the same as the stored password (112) the "YES" branch is followed and normal operation resumes (104). Otherwise, the "NO" branch is followed and access is denied (114). As is well known in the art, instead of
5 denying access upon the first input of an erroneous password, a further try or several further tries may be permitted up to a predetermined number of attempts with an incremented tamper count upon each failed password entry. In addition to denying access, alerts or alarms may be
10 activated.

In the method and corresponding device described above, since the usual implementation is upon a digital computer, a de-bug program can be run alongside the password
15 protection. As part of which, the de-bug program can, upon entry of any password, follow the program to the memory location at which the correct password is stored for comparison purposes. The de-bug program can then be used to copy the stored password from that memory location for
20 correct entry. In this way, the prior art method and corresponding device described above is vulnerable to attack and to the bypass of the password security even if the data is encrypted.

25 It is an aim of preferred embodiments of the present invention to obviate or overcome at least one disadvantage encountered in relation to the prior art, whether referred to herein or otherwise.

30 Summary of the Invention

According to the present invention in a first aspect there is provided an access control device comprising means

for receiving an input password, means for combining the input password with a pre-selected code thereby to produce a combined password, and means for decrypting encrypted code using the combined password.

5

Suitably, the apparatus further comprises means for encrypting the combined password and the encrypted combined password is used for decryption.

10 According to the present invention in a second aspect, there is provided a method of controlling access, which method comprises the steps of receiving an input password, combining the input password with a predetermined code to produce a combined password, and decrypting encrypted code
15 using the combined password.

Suitably, the combined password is encrypted and the encrypted combined password is used for decrypting encrypted code.

20

Suitably, the encrypted combined password is a key for decryption of the encrypted code.

Suitably, the password is an alphanumeric string.
25 Suitably, the code is an alphanumeric string.

Suitably, the pre-stored access password comprises a pre-selected password combined with the predetermined code, which combination is encrypted.

30

Normally the combined pre-selected password is encrypted according to the encryption algorithm used for the combined password. Suitably, the encryption is

substantially unreversible (asymmetric). Typically, the encryption algorithm will be a public key algorithm.

According to the present invention in a third aspect;
5 there is provided a computer program for executing the method of the second aspect of the invention.

According to the present invention in a fourth aspect,
there is provided a carrier comprising a computer program
10 according to the third aspect of the invention.

Brief Description of the Figures

The present invention will now be described, by way of
15 example only, with reference to the drawings that follow;
in which:

Figure 1 is a representative flow diagram of a prior
art access control method.

20

Figure 2 is a representative functional flow diagram of
an access control method according to the present
invention.

25 Description of the Preferred Embodiments

Referring to Figure 2 of the drawings that follow,
there is shown a flow diagram illustrating a method
according to the present invention, according to which
30 method a corresponding device may operate.

At (200) a password is selected. As with the prior device and method, the password may be user-selected or chosen in some other way.

5 The selected password is then combined with (202) with a longer password string at pre-selected locations therewithin. This produces a combined password which is encoded (204). Normally, the encoding step will comprise a public key, substantially irreversible, encryption, but in
10 theory could be as simple as carrying out an AND or XOR operation.

The encrypted combined password is ^φ used as an encryption key to encrypt data (206) which may be software.
15 Notably, the encrypted combined password is not stored in any memory location. Following this the device enters normal operation (208) as part of which it checks (210) whether a requested data/software access is password protected. If the access is not password protected the
20 "NO" branch is followed back to normal operation. Otherwise, the "YES" branch is followed and a request is made for a password to be input (212). Upon input of a password, it is inserted into pre-selected locations of the predetermined string (214). This is the same predetermined
25 string with which the original password is combined (202). This produces a combined password which is encrypted at (216) using the same encryption as at (204).

The encrypted combined password is used as a decryption
30 key to decrypt the encrypted data/software to which access is sought. Therefore only entry of a correct password will properly decrypt the data/software.

By way of example, therefore, at step (200), the password "FRED" may be entered by a user. The selected password is combined with the string A7BX2Q66FEAR3YD at locations subsequent to characters 2, 6, 9 and 13 (by order). This produces (202) the following combined result:
A7FBXS2RQ66EFEARD3YD. The underlined letters are the password letters inserted at pre-selected points within the longer string. They are underlined for the purposes of explanation only.

10

At step (204), the combined password is encrypted according to any encryption method. Preferably, a public key encryption is used but this need not be the case. This may result in an output as follows: 3XTAV2?8BAD99X. The encrypted result need not be the same length as the combined password. The encrypted combined password is then used as an encryption key to encrypt data or software. If password protected access is sought (210), an input password is requested (212). Here, if an incorrect password is entered, for instance "MOUSE" it will be combined (214) with the pre-selected string at the pre-selected locations to give the following result A7MBXS2OQ66UFEARS3YED. This combined input password is then encrypted (216) according to the same encryption used at step (204) and used as a decryption key to decrypt the encrypted data. As the key is wrong the decryption will be inaccurate.

In the case of the correct password "FRED" being input at (212), it will be inserted at corresponding locations encrypted and will correspond to the key used for encryption. Thus when used as a decryption key it will accurately decrypt the data.

Accordingly, neither the password to be used by the user nor the decryption key is not stored anywhere within the device. Thus, by inspection of the device running a
5 for instance, de-bug program, an unauthorised user would not be able to gain access to the necessary password nor to the decryption key.

Although reference is made herein to "passwords" it
10 will be appreciated that this could be any signal or combination of signals and need not be a word at all.

A device operating as set out above with reference to preferred embodiments of the invention may be embodied in
15 computer software in a digital computer or otherwise, for instance on a carrier such as a floppy disk, compact disk or hard drive.

The reader's attention is directed to all papers
20 and documents which are filed concurrently with or previous to this specification in connection with this application and which are open to public inspection with this specification, and the contents of all such papers and documents are incorporated herein by reference.

25

All of the features disclosed in this specification (including any accompanying claims, abstract and drawings), and/or all of the steps of any method or process so disclosed, may be combined in any combination, except
30 combinations where at least some of such features and/or steps are mutually exclusive.

Each feature disclosed in this specification (including any accompanying claims, abstract and drawings), may be replaced by alternative features serving the same, equivalent or similar purpose, unless expressly stated
5 otherwise. Thus, unless expressly stated otherwise, each feature disclosed is one example only of a generic series of equivalent or similar features.

The invention is not restricted to the details of the
10 foregoing embodiment(s). The invention extends to any novel one, or any novel combination, of the features disclosed in this specification (including any accompanying claims, abstract and drawings), or to any novel one, or any novel combination, of the steps of any method or process so
15 disclosed.

Claims

1. An access control device comprising means for receiving
5 an input password, means for combining the input password with a pre-selected code thereby to produce a combined password, and means for decrypting encrypted code using the combined password.
- 10 2. An access control device according to claim 1, in which the apparatus further comprises means for encrypting the combined password and the encrypted combined password is used for decryption.
- 15 3. A method of controlling access, which method comprises the steps of receiving an input password, combining the input password with a predetermined code to produce a combined password, and decrypting encrypted code using the combined password.
- 20 4. A method of controlling access according to claim 3, in which the combined password is encrypted and the encrypted combined password is used for decrypting encrypted code.
- 25 5. A method of controlling access according to claim 3 or claim 4, in which the encrypted combined password is a key for decryption of the encrypted code.
- 30 6. A method of controlling access according to any one of claims 3 to 5, in which the password is an alphanumeric string.

7. A method of controlling access according to claim 6, in which the code is an alphanumeric string.

8. A method of controlling access according to any
5 preceding claim, in which the pre-stored access password comprises a pre-selected password combined with the predetermined code, which combination is encrypted.

9. A method of controlling access according to claim 8, in
10 which the combined pre-selected password is encrypted according to the encryption algorithm used for the combined password.

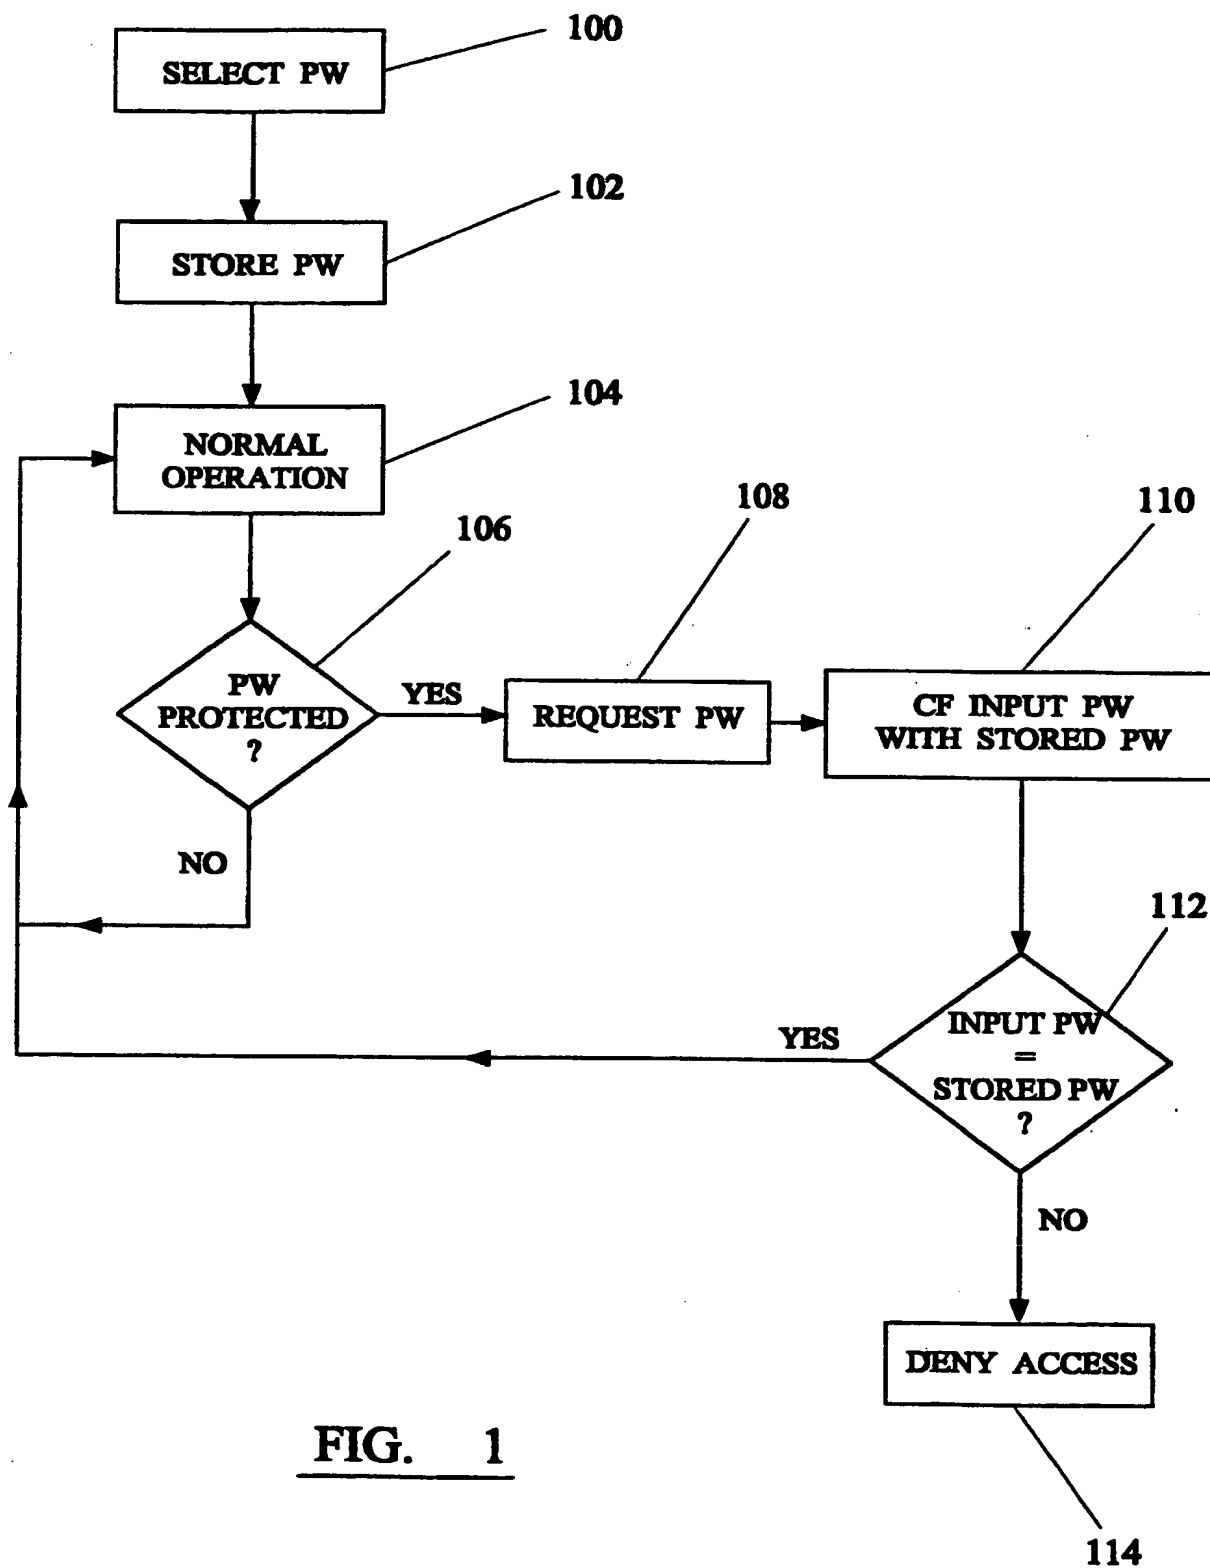

10. A method of controlling access according to claim 9, in
15 which the encryption is substantially unreversible (asymmetric).

11. A method of controlling access according to claim 10,
in which the encryption algorithm will be a public key
20 algorithm.

12. A computer program for carrying out the method of any one of claims 3 to 11.

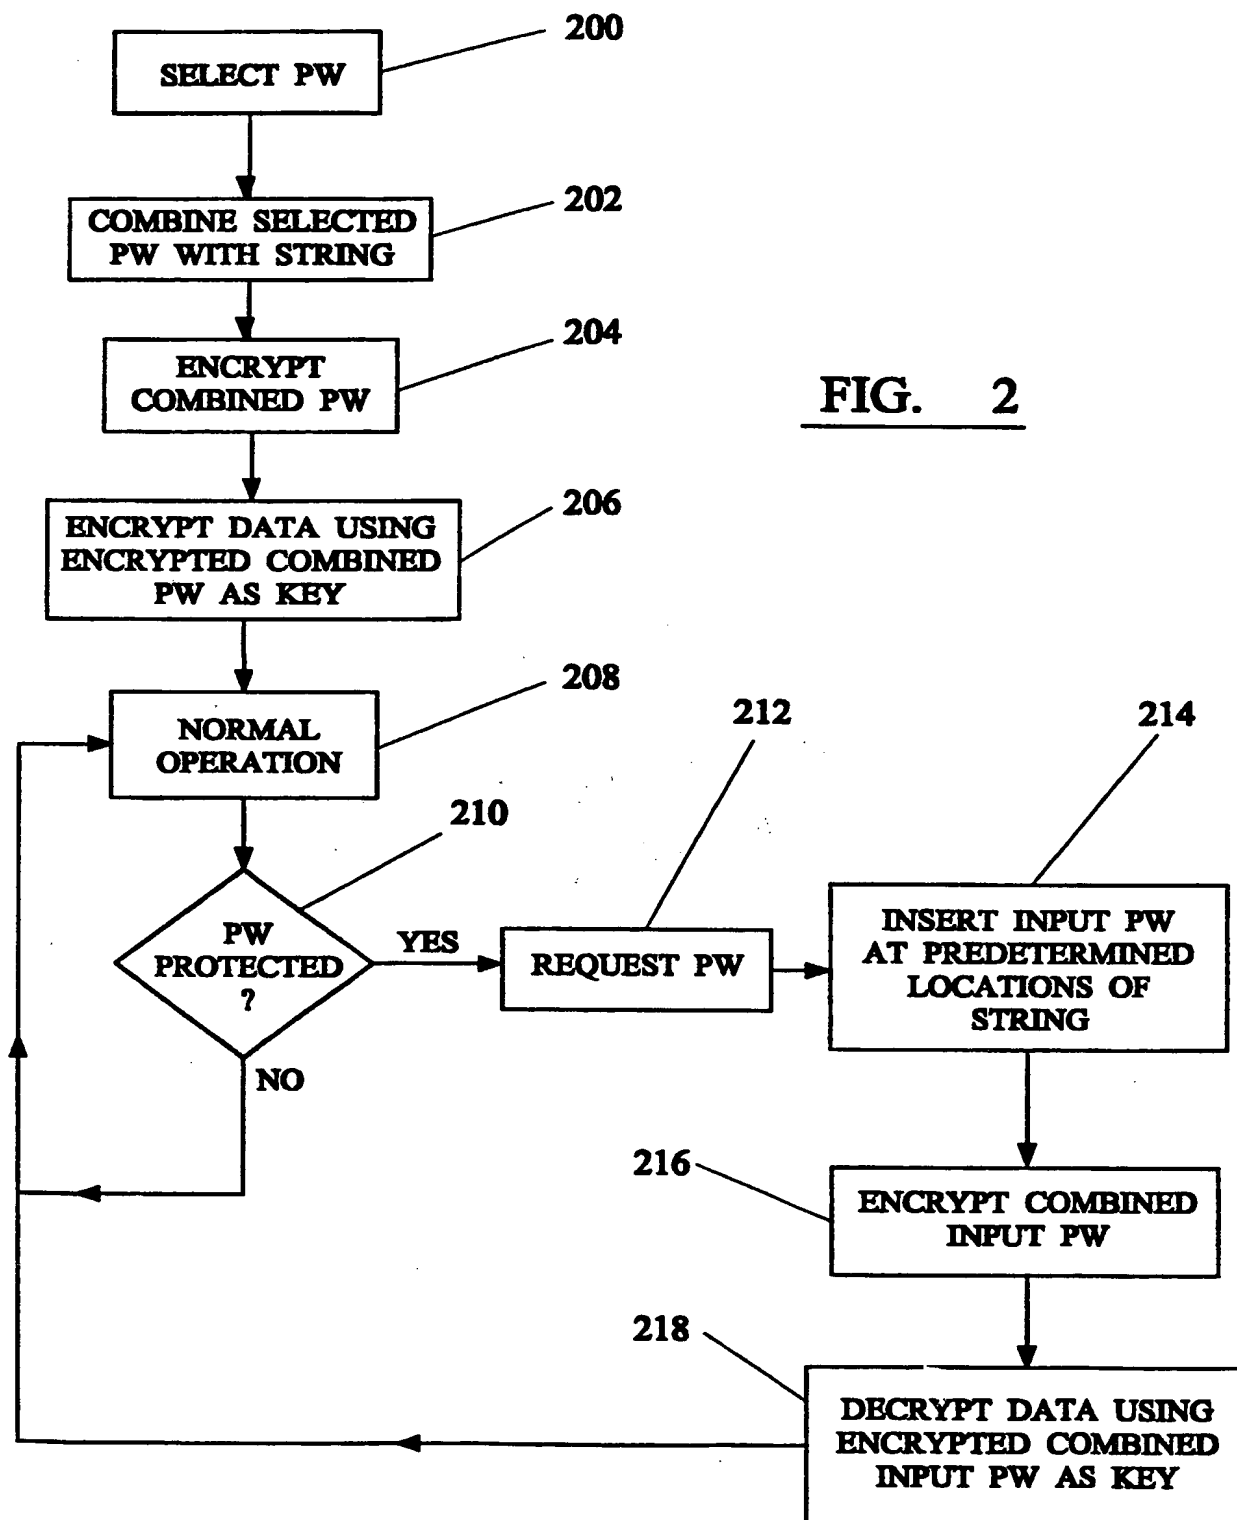

25 13. A carrier comprising a computer program according to claim 12.
